

A PIECEWISE POLYNOMIAL APPROXIMATION TO THE SOLUTION OF AN INTEGRAL EQUATION WITH WEAKLY SINGULAR KERNEL

G. VAINIKKO and P. UBA

(Received 22 July 1980)

(Revised 5 February 1981)

Abstract

We construct collocation methods with an arbitrary degree of accuracy for integral equations with logarithmically or algebraically singular kernels. Superconvergence at collocation points is obtained. A grid is used, the degree of non-uniformity of which is in good conformity with the smoothness of the solution and the desired accuracy of the method.

1. The integral equation

Consider the integral equation

$$u(t) = \int_0^b \kappa(|t-s|)u(s) ds + f(t), \quad (1.1)$$

with an m times, $m \geq 2$, continuously differentiable absolute term on $[0, b]$ and with an $m-1$ times continuously differentiable kernel on $(0, b]$, satisfying

$$|\kappa(t)| \leq c(|\ln t| + 1) \quad \text{and} \quad |\kappa^{(k)}(t)| \leq ct^{-k} \quad \text{for } k = 1, \dots, m-1 \quad (1.2)$$

or

$$|\kappa^{(k)}(t)| \leq ct^{-k-\alpha}, \quad 0 < \alpha < 1, \quad \text{for } k = 0, 1, \dots, m-1. \quad (1.3)$$

We assume that the corresponding homogeneous integral equation has only the trivial solution. In this case equation (1.1) has a unique solution u , where

$u \in C[0, b] \cap C^m(0, b)$ and (see [4])

$$|u^{(k)}(t)| \leq c_0(t^{-k-\alpha+1} + (b-t)^{-k-\alpha+1}),$$

$$k = 1, \dots, m \quad \text{and} \quad c_0 = \text{constant}; \quad (1.4)$$

in the case (1.2) of logarithmic singularity, these estimates hold with $\alpha = 0$ for $k = 2, \dots, m$, and

$$|u'(t)| \leq c_0(|\ln t| + |\ln(b-t)|).$$

On the basis of this information, collocation methods on non-uniform grids with piecewise polynomial approximation of the solution are constructed.

As break points of a piecewise polynomial approximation we choose

$$\text{and} \quad \left. \begin{aligned} t_i &= (b/2)(i/n)^r, & i &= 0, 1, \dots, n, \\ t_{n+i} &= b - t_{n-i}, & i &= 1, \dots, n, \end{aligned} \right\} \quad (1.5)$$

where $r \in R$, $r > 1$, characterizes the degree of non-uniformity of the grid. The break points are located symmetrically with regard to the centre of the interval $[0, b]$, with a greater density towards its ends, and

$$t_{i+1} - t_i \leq \frac{b}{2} \frac{r}{n} \left(\frac{i+1}{n} \right)^{r-1}, \quad i = 0, 1, \dots, n-1. \quad (1.6)$$

Analogous estimates are valid for the break points on the other half of the interval $[0, b]$.

2. The first method

We define some interpolation points in the standard interval $[-1, 1]$:

$$-1 < \tau_1 < \tau_2 < \dots < \tau_m < 1. \quad (2.1)$$

By the linear transformation

$$\tau_{ik} := t_i + (\tau_k + 1)(t_{i+1} - t_i)/2, \quad k = 1, \dots, m, \quad i = 0, 1, \dots, 2n-1, \quad (2.2)$$

we transfer these points into the interval $[t_i, t_{i+1}]$. It is clear that

$$t_i < \tau_{i1} < \tau_{i2} < \dots < \tau_{im} < t_{i+1}, \quad i = 0, 1, \dots, 2n-1.$$

We construct the approximate solution u_n of equation (1.1) as a piecewise polynomial function of degree $m-1$ with break points (1.5); at points t_i , $i = 1, \dots, 2n-1$, the function u_n may be discontinuous. It is required that u_n should satisfy equation (1.1) at the interpolation points:

$$u_n(\tau_{ik}) = \int_0^b \kappa(|\tau_{ik} - s|) u_n(s) ds + f(\tau_{ik}),$$

$$k = 1, \dots, m, \quad i = 0, 1, \dots, 2n-1. \quad (2.3)$$

The conditions (2.3) form a linear system of equations whose exact form is determined by the choice of a basis in the subspace of the piecewise polynomial functions. For example, taking u_n in each subinterval in the form

$$u_n(t) = \sum_{l=1}^m a_{jl} \varphi_{jl}(t), \quad t_j \leq t \leq t_{j+1},$$

where φ_{jl} are the Lagrange fundamental polynomials ($\varphi_{jl}(\tau_{jk}) = \delta_{kl}$, for $k, l = 1, \dots, m$) of degree $m - 1$, the conditions (2.3) lead to the system of equations

$$a_{ik} = \sum_{j=0}^{2n-1} \sum_{l=1}^m \int_{t_j}^{t_{j+1}} \kappa(|\tau_{ik} - s|) \varphi_{jl}(s) ds \cdot a_{jl} + f(\tau_{ik})$$

with respect to the unknown coefficients a_{ik} , $k = 1, \dots, m$, $i = 0, 1, \dots, 2n - 1$.

3. The second method

We choose the interpolation points τ_k , $k = 1, \dots, m$, in the standard interval $[-1, 1]$ so that (compare with (2.1))

$$-1 = \tau_1 < \tau_2 < \dots < \tau_m = 1, \quad (3.1)$$

and transfer them according to formula (2.2) into the interval $[t_i, t_{i+1}]$. It is clear that now

$$t_i = \tau_{i1} < \tau_{i2} < \dots < \tau_{im} = t_{i+1}, \quad i = 0, 1, \dots, 2n - 1.$$

The approximate solution u_n of equation (1.1) is constructed in the form of a continuous piecewise polynomial function of degree $m - 1$, with break points (1.5). It is required that u_n should satisfy equation (1.1) in the interpolation points, that is, conditions (2.3) should be satisfied, with the reservation that these conditions are taken only once for the break points $t_i = \tau_{i-1,m} = \tau_{i1}$, $i = 1, \dots, 2n - 1$.

4. Formulation of the main result

THEOREM. *Let the conditions for f, κ and equation (1.1) presented in Section 1 be satisfied. In the case of the validity of condition (1.2) put $\alpha = 0$. Then, for sufficiently large n , either of the two methods described in Sections 2 and 3 determines a unique approximate solution u_n . If*

$$r = \mu / (1 - \alpha) \geq 1, \quad \mu < m, \quad (4.1)$$

then

$$\sup_{0 < t < b} |u_n(t) - u(t)| \leq (\text{constant})n^{-\mu} \quad (4.2)$$

and

$$\max_{\substack{0 < i < 2n-1 \\ 1 < k < m}} |u_n(\tau_{ik}) - u(\tau_{ik})| \leq (\text{constant})\varepsilon_n, \quad (4.3)$$

where

$$\varepsilon_n = \begin{cases} n^{-m}(\ln n)^\alpha & \text{for } \mu > m/2, \\ n^{-m} \ln n & \text{for } \mu = m/2, \\ n^{-2\mu}(\ln n)^\alpha & \text{for } \mu < m/2, \end{cases} \quad (4.4)$$

in the case of (1.3) and

$$\varepsilon_n = \begin{cases} n^{-m} \ln n & \text{for } \mu > m/2, \\ n^{-m}(\ln n)^2 & \text{for } \mu = m/2, \\ n^{-2\mu} \ln n & \text{for } \mu < m/2 \end{cases} \quad (4.5)$$

in the case of (1.2).

The proof is presented in Sections 5 and 6. We shall not specify the constants in (4.2) and (4.3), but note here that, by increasing r , they also increase, and thus the superconvergence at interpolation points is highly useful: to attain a method of m th degree of accuracy in the uniform norm we must choose $\mu = m$ and $r = m/(1 - \alpha)$ whereas, to attain nearly the same accuracy at the interpolation points, it is sufficient to put $\mu = m/2$ and $r = m/(2(1 - \alpha))$.

Numerical testing of the described methods will be undertaken in the future. In the case where $m = 2$, the method described in Section 3 reduces to the piecewise linear collocation method. This method for the uniform grid (in our notation $r = 1$) is investigated in [2]. Our result for $m = 2$ and $r = 1$ is consistent with the results of [2]. Numerical calculations confirm the superconvergence at the points of interpolation (see [2]). The theorem was announced in [5]. We refer also to Rice [3], who appears to have been the first to study graded grids for approximation of functions with singularities.

5. Transition to the operator equation

Let us denote by T the integral operator of equation (1.1). Then (1.1) can be considered as the equation

$$u = Tu + f \quad (5.1)$$

in the Banach space $E = L_\infty$ with the norm $\|u\| = \sup_{0 \leq t \leq b} |u(t)|$. Both methods for the solution of (1.1) described above are equivalent to the solution of equation

$$u_n = P_n T u_n + P_n f, \quad (5.2)$$

where $P_n = P_{n,m}$ is the interpolation projector assigning to any continuous function u its piecewise polynomial interpolant:

$$(P_n u)(t) = \sum_{k=1}^m u(\tau_{ik}) \varphi_{ik}(t) \quad \text{for } t_i \leq t \leq t_{i+1}, i = 0, 1, \dots, 2n-1;$$

the interpolant is determined in each interval $[t_i, t_{i+1}]$ independently; $P_n u$ is discontinuous or continuous in break points t_i , depending on the choice of (2.1) or (3.1), respectively.

The norms $\|P_n\|$ are uniformly bounded, $\|P_n\| = \|P\|$, $n = 1, 2, \dots$, where P is the Lagrange interpolation projector of degree $m-1$ on $[-1, 1]$ defined by interpolation points (2.1) or (3.1). It is easy to see that $\|P_n u - u\|_{L_\infty} \rightarrow 0$ as $n \rightarrow \infty$ for $u \in E' = C[0, b]$.

Since T is a compact operator from L_∞ into C , we conclude by means of standard arguments (see [1], Lemma 15.5) that $\|P_n T - T\|_{L_\infty \rightarrow L_\infty} \rightarrow 0$ as $n \rightarrow \infty$. Now, from the unique solvability of (5.1), it follows that (5.2) is uniquely solvable for sufficiently large n , $n \geq n_0$, whereby

$$\|u_n - u\|_{L_\infty} \leq c_1 \|u - P_n u\|_{L_\infty}, \quad c_1 = \sup_{n \geq n_0} \|(I - P_n T)^{-1}\| < \infty. \quad (5.3)$$

In addition to this traditional estimate we need an estimate

$$\|u_n - P_n u\|_{L_\infty} \leq c_2 \|T(u - P_n u)\|_{L_\infty}, \quad c_2 = c_1 \|P\|, \quad (5.4)$$

which follows from equalities $u_n - P_n u = P_n T(u_n - u)$, $u_n - u = (I - P_n T)^{-1}(P_n u - u)$ and $u_n - P_n u = (I - P_n T)^{-1} P_n T(P_n u - u)$.

6. Error estimates for the piecewise polynomial interpolant

Let u be any function satisfying (1.4).

PROPOSITION 1. *If $r = \mu/(1 - \alpha) \geq 1$ and $\mu \leq m$ then*

$$\|u - P_n u\|_{L_\infty} \leq c_3 n^{-\mu} \quad \text{where } c_3 = \text{constant}. \quad (6.1)$$

PROOF. The well-known inequality $\|u - P_n u\| \leq (1 + \|P_n\|) \text{dist}(u, P_n E)$ can be reduced to the form

$$\begin{aligned} \|u - P_n u\|_{L_\infty} &\leq (1 + \|P\|) \max_{0 \leq i \leq 2n-1} \eta_i, \\ \eta_i &= \inf_{v \in \pi_{m-1}} \max_{t_i \leq t \leq t_{i+1}} |u(t) - v(t)|, \end{aligned}$$

where π_{m-1} denotes the set of the polynomials of degree $\leq m-1$. We prove the inequalities

$$\eta_i \leq c_4 n^{-\mu} (i+1)^{\mu-m}, \quad i = 0, 1, \dots, n-1, \quad (6.2)$$

and similar inequalities for the other half of the interval $[0, b]$, that is, for $i = n, \dots, 2n-1$. By (1.4) to (1.6), the known estimate $\eta_i \leq \gamma_m \max_{t_i \leq t \leq t_{i+1}} |u^{(m)}(t)| (t_{i+1} - t_i)^m$, where $\gamma_m = 2^{1-2m}/(m!)$ for $1 \leq i \leq n-1$, can be rewritten as

$$\begin{aligned} \eta_i &\leq \gamma_m 2c_0 (b/2)^{-m-\alpha+1} (n/i)^{r(m+\alpha-1)} (b/2)^m (r/n)^m ((i+1)/n)^{(r-1)m} \\ &= 2c_0 \gamma_m (b/2)^{1-\alpha} r^m n^{-\mu} (i+1)^{\mu-m} ((i+1)/i)^{rm-\mu} \leq c_4 n^{-\mu} (i+1)^{\mu-m}. \end{aligned}$$

To estimate η_0 , it is sufficient to take $v(t)$ as a constant or a linear function. In the case of $\alpha > 0$, by (1.4) and (1.5),

$$\begin{aligned} \eta_0 &\leq \max_{0 \leq t \leq t_1} |u(t) - u(0)| \leq \int_0^{t_1} |u'(s)| ds \\ &\leq \frac{c_0}{1-\alpha} t_1^{1-\alpha} = \frac{c_0}{1-\alpha} (b/2)^{1-\alpha} n^{-\mu}; \end{aligned}$$

in the case of $\alpha = 0$, we put $v(t) = u(0) + (u(t_1) - u(0))(t/t_1)$; therefore

$$\begin{aligned} |u(t) - v(t)| &= \left| \int_0^t u'(s) ds - \frac{t}{t_1} \int_0^{t_1} u'(s) ds \right| \\ &= \left| \int_0^t \left[u'(s) - u'\left(\frac{t_1}{t}s\right) \right] ds \right| = \left| \int_0^t ds \int_s^{t_1 s/t} u''(\tau) d\tau \right| \\ &\leq c_0 \int_0^t ds \int_s^{t_1 s/t} \frac{d\tau}{\tau} = c_0 \int_0^t \left(\ln\left(\frac{t_1}{t}s\right) - \ln(s) \right) ds = c_0 t \ln \frac{t_1}{t} \end{aligned}$$

and

$$\begin{aligned} \eta_0 &\leq \max_{0 \leq t \leq t_1} |u(t) - v(t)| \leq c_0 \max_{0 \leq t \leq t_1} t \ln \frac{t_1}{t} \\ &= c_0 e^{-1} t_1 = c_0 e^{-1} (b/2) n^{-\mu}. \end{aligned}$$

That completes the proof of the estimate (6.2). Estimate (6.1) follows from (6.2) and similar estimates for $i = n, \dots, 2n-1$. Thus Proposition 1 is proved.

PROPOSITION 2. If $r = \mu/(1-\alpha) \geq 1$, $\mu \leq m$ and $p = 1/(1-\alpha)$, then

$$\|u - P_n u\|_{L_p(0,b)} \leq c_{5,\mu} \delta_n,$$

where

$$\delta_n = \begin{cases} n^{-m} & \text{for } \mu > m/2, \\ n^{-m} (\ln n)^{1-\alpha} & \text{for } \mu = m/2, \\ n^{-2\mu} & \text{for } \mu < m/2. \end{cases} \quad (6.3)$$

PROOF. It is clear that

$$\begin{aligned} \|u - P_n u\|_{L_p(0,b)} &\leq \left\{ \sum_{i=0}^{2n-1} (t_{i+1} - t_i) \max_{t_i \leq t \leq t_{i+1}} |u(t) - (P_n u)(t)|^p \right\}^{1/p} \\ &\leq (1 + \|P\|) \left\{ \sum_{i=0}^{2n-1} (t_{i+1} - t_i) \eta_i^p \right\}^{1/p}. \end{aligned}$$

By (6.2) and (1.6)

$$\|u - P_n u\|_{L_p(0,b/2)} \leq (1 + \|P\|) c_4 \left(\frac{br}{2} \right)^{1/p} n^{-\mu} \left\{ \sum_{i=0}^{n-1} n^{-r} (i+1)^{r-1-(m-\mu)p} \right\}^{1/p},$$

and a similar estimate holds for the other half of the interval. Now estimates (6.3) follow, because

$$\begin{aligned} \mu > m/2 &\Rightarrow r - 1 - (m - \mu)p > -1, \quad \sum_{i=0}^{n-1} (i+1)^{r-1-(m-\mu)p} \leq c_{6,\mu} n^{r-(m-\mu)p}; \\ \mu = m/2 &\Rightarrow r - 1 - (m - \mu)p = -1, \quad \sum_{i=0}^{n-1} (i+1)^{r-1-(m-\mu)p} \leq c_6 \ln n; \\ \mu < m/2 &\Rightarrow r - 1 - (m - \mu)p < -1, \quad \sum_{i=0}^{n-1} (i+1)^{r-1-(m-\mu)p} \leq c_{6,\mu}. \end{aligned}$$

Thus Proposition 2 is proved.

PROPOSITION 3. If $r = \mu/(1 - \alpha) \geq 1$, $\mu \leq m$, then

$$\|T(u - P_n u)\|_{L_\infty} \leq c_{7,\mu} \varepsilon_n, \quad (6.4)$$

where ε_n is determined by (4.4) or (4.5).

PROOF. Let $\alpha > 0$. For $p = 1/(1 - \alpha)$ and $q = 1/\alpha$ it holds that

$$\begin{aligned} \|T(u - P_n u)\|_{L_\infty} &= \sup_{0 \leq t \leq b} \left| \int_0^b \kappa(|t - s|) [u(s) - (P_n u)(s)] ds \right| \\ &\leq \|u - P_n u\|_{L_\infty} \sup_{0 \leq t \leq b} \int_{\substack{s \in [0, b] \\ |s - t| \leq h}} |\kappa(|t - s|)| ds \\ &\quad + \|u - P_n u\|_{L_p} \left\{ \int_{\substack{s \in [0, b] \\ |s - t| > h}} |\kappa(|t - s|)|^q ds \right\}^{1/q}. \end{aligned}$$

By means of (1.3) and Propositions 1 and 2 this can be reduced to

$$\|T(u - P_n u)\|_{L_\infty} \leq c_{8,\mu} (n^{-\mu} h^{1-\alpha} + \delta_n |\ln h|^\alpha). \quad (6.5)$$

Choosing h in the case $\mu \geq m/2$ such that $h^{1-\alpha} = n^{\mu-m}$ and in the case $\mu < m/2$ such that $h^{1-\alpha} = n^{-\mu}$, we obtain the estimates (6.4) and (4.4).

In the case of $\alpha = 0$, instead of (6.5) we have $\|T(u - P_n u)\|_{L_\infty} < c_{8,\mu}(n^{-\mu}h|\ln h| + \delta_n|\ln h|)$ and the proof of the estimates (6.4) and (4.5) is analogous to the one above. Thus Proposition 3 is proved.

To complete the proof of the theorem, note that we obtain (4.2) immediately from (5.3) and (6.1). From (5.4) and (6.4) we get (4.3), since

$$|u_n(\tau_{ik}) - u(\tau_{ik})| \leq \|u_n - P_n u\|_{L_\infty}.$$

The proof of the theorem is now complete.
